Noise Reduction Advantages of Insulated Doors

Lets face it, peace and quiet are becoming precious commodities these days. Whether youre battling the roar of city traffic, the neighbors latenight jam sessions, or just trying to escape the relentless racket of a busy household, finding a sanctuary of silence can feel like a Herculean task. Thats where the often-overlooked hero of home tranquility comes in: the humble insulated door.

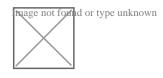

We often think of insulation in terms of keeping us warm in winter and cool in summer, and thats certainly a major benefit. But the noise reduction advantages of insulated doors are equally compelling, and often underestimated. Think of it this way: a poorly insulated door is essentially a thin membrane, vibrating and transmitting sound waves right into your living space. Its like having a built-in speaker for the outside world, blasting unwanted noise directly into your ears.

An insulated door, on the other hand, acts as a formidable sound barrier. The dense materials and construction used in these doors – often a combination of solid core, foam insulation, and tight seals – are designed to absorb and deflect sound waves, rather than transmit them. Imagine the difference between shouting at a brick wall versus shouting at a thin sheet of plywood. The brick wall absorbs much of the sound, deadening the noise. An insulated door functions similarly.

The benefits of this noise reduction are numerous. Improved sleep is a big one. Reduced noise pollution can lead to deeper, more restorative sleep, allowing you to wake up feeling refreshed and ready to tackle the day. For those who work from home, an insulated door can create a more focused and productive workspace, minimizing distractions and allowing for better concentration. Even simple things like enjoying a quiet evening reading or having a conversation without shouting over the din become more pleasurable.

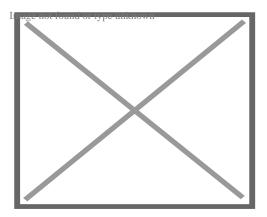

Beyond personal comfort, insulated doors can also increase the value of your property. A quieter home is a more desirable home, particularly in noisy urban environments. Potential buyers will appreciate the peace and quiet offered by insulated doors, making your home more attractive in a competitive market. Choosing the right insulated door for noise reduction involves considering a few factors. The thickness and density of the door are crucial, as is the quality of the weather stripping around the frame. Look for doors with a high Sound Transmission Class (STC) rating – the higher the STC rating, the better the door is at blocking sound.

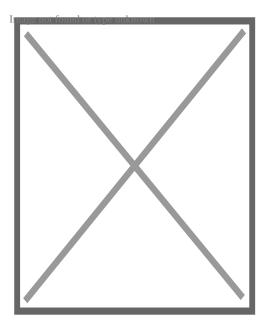

In conclusion, while the energy-saving benefits of insulated doors are widely recognized, their noise reduction capabilities are a significant and often overlooked advantage. Investing in an insulated door is an investment in your peace of mind, your sleep quality, and ultimately, your overall well-being. Its a simple upgrade that can make a world of difference in creating a more comfortable and tranquil living environment. So, the next time youre looking to improve your home, dont forget to consider the quiet power of an insulated door. Your ears will thank you.

Environmental Impact of Different Door Materials

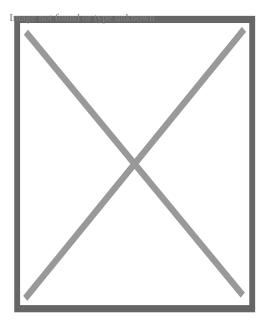

About Keypad

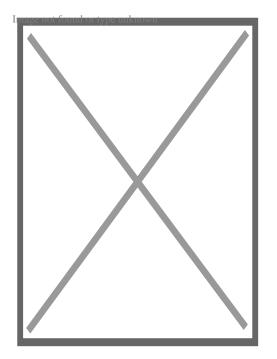

A telephone keypad using the ITU E.161 standard.

Numeric keypad, integrated with a computer keyboard

A calculator

1984 flier for projected capacitance keypad

A **keypad** is a block or pad of buttons set with an arrangement of digits, symbols, or alphabetical letters. Pads mostly containing numbers and used with computers are numeric keypads. Keypads are found on devices which require mainly numeric input such as calculators, television remotes, push-button telephones, vending machines, ATMs, point of sale terminals, combination locks, safes, and digital door locks. Many devices follow the E.161 standard for their arrangement.

Uses and functions

[edit]

A computer keyboard usually has a small numeric keypad on the side, in addition to the other number keys on the top, but with a calculator-style arrangement of buttons that allow more efficient entry of numerical data. This number pad (commonly abbreviated to *numpad*) is usually positioned on the right side of the keyboard because most people are right-handed.

Many laptop computers have special function keys that turn part of the alphabetical keyboard into a numerical keypad as there is insufficient space to allow a separate keypad to be built into the laptop's chassis. Separate external plug-in keypads can be purchased.

Keypads for the entry of PINs and for product selection appear on many devices including ATMs, vending machines, point of sale payment devices, time clocks, combination locks and digital door locks.

Keypad technologies

[edit]

Apart from mechanical keypads, [1][2][3] there are a wide range of technologies that can be used as keypads, each with distinctive advantages and disadvantages. These include Resistive, [4] Capacitive, [5] Inductive, [6] Piezoelectric, [7] and Optical. [8]

Key layout

[edit]

Further information: Telephone keypad § Layout

The first key-activated mechanical calculators and many cash registers used "parallel" keys with one column of 0 to 9 for each position the machine could use. A smaller, 10-key input first started on the Standard Adding Machine in 1901.⁹] The calculator had the digit keys arranged in one row, with zero on the left, and 9 on the right. The modern four-row arrangement debuted with the Sundstrand Adding

Machine in 1911.[¹⁰]

There is no standard for the layout of the four arithmetic operations, the decimal point, equal sign or other more advanced mathematical functions on the keypad of a calculator.

The invention of the push-button telephone keypad is attributed to John E. Karlin, an industrial psychologist at Bell Labs in Murray Hill, New Jersey. $[^{11}][^{12}]$ On a telephone keypad, the numbers 1 through 9 are arranged from left to right, top to bottom with 0 in a row below 789 and in the center. Telephone keypads also have the special buttons labelled * (star) and # (octothorpe, number sign, "pound", "hex" or "hash") on either side of the zero key. The keys on a telephone may also bear letters which have had several auxiliary uses, such as remembering area codes or whole telephone numbers.

The layout of calculators and telephone number pads diverged because they developed at around the same time. The phone layout was determined to be fastest by Bell Labs testing for that application, and at the time it controlled all the publicly connected telephones in the United States.

Origin of the order difference

[edit]

Although calculator keypads pre-date telephone keypads by nearly thirty years, the top-to-bottom order for telephones was the result of research studies conducted by a Bell Labs Human Factors group led by John Karlin. They tested a variety of layouts including a Facit like the two-row arrangement, buttons in a circle, buttons in an arc, and rows of three buttons.[¹¹] The definitive study was published in 1960:

"Human Factor Engineering Studies of the Design and Use of Pushbutton Telephone Sets" by R. L. Deininger.[¹³][¹⁴] This study concluded that the adopted layout was best, and that the calculator layout was about 3% slower than the adopted telephone keypad.

Despite the conclusions obtained in the study, there are several popular theories and folk histories explaining the inverse order of telephone and calculator keypads.

- One popular theory suggests that the reason is similar to that given for the QWERTY layout, the unfamiliar ordering slowed users to accommodate the slow switches of the late 1950s and early 1960s.[¹⁵]
- Another explanation proposed is that at the time of the introduction of the telephone keypad, telephone numbers in the United States were commonly given out using alphabetical characters for the first two digits. Thus 555-1234 would be given out as KL5-1234. These alpha sequences were mapped to words. "27" was given out as "CRestview", "28" as "ATwood", etc. By placing the "1" key in the upper left, the alphabet was arranged in the normal left-to-right descending order for English characters. Additionally, on a rotary telephone, the "1" hole was at the top, albeit at the top right.

Keypad track design

[edit]

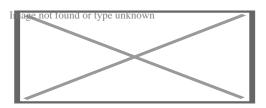

Figure 1. Keypad wiring methods: separate connections (left), x/y multiplexing (center), Charlieplexing (right).

Separate connections

[edit]

A mechanically-switched 16-key keypad can be connected to a host through 16 separate connecting leads, plus a ground lead (Figure 1, left). Pressing a key will short to ground, which is detected by the host. This design allows any number or combination of keys can be pressed simultaneously. Parallel-in serial-out shift registers may be used to save I/O pins.

X/Y multiplexing

[edit]

See also: Keyboard matrix circuit

These 16 + 1 leads can be reduced to just 8 by using x/y multiplexing (Figure 1, center). A 16-key keypad uses a 4 × 4 array of 4 I/O lines as outputs and 4 as inputs. A circuit is completed between an output and an input when a key is pressed. Each individual keypress creates a unique signal for the host. If required, and if the processor allows, two keys can be pressed at the same time without ambiguity. Adding diodes in series with each key prevents key ghosting, allowing multiple simultaneous presses.

Charlieplexing

[edit] Main article: Charlieplexing 8 leads can detect many more keys if tri-state multiplexing (Figure 1, right) is used instead, which enables $(n-1) \times (n/2)$ keys to be detected with just $n \mid /O$ lines. 8 \mid /O can detect 28 individual keys without ambiguity. Issues can occur with some combinations if two keys are pressed simultaneously. If diodes are used, then the number of unique keys detectable is doubled.[¹⁶]

About Maintenance

"Repair" and "repairman" redirect here. For home repair, see Home repair. For the Wikipedia administrative page, see Wikipedia:Maintenance. For other topics about maintenance, see Maintenance (disambiguation).

A tractor being mechanically repaired in Werneuchen, 1966

Field repair of aircraft engine (1915–1916)

The technical meaning of **maintenance** involves functional checks, servicing, repairing or replacing of necessary devices, equipment, machinery, building infrastructure and supporting utilities in industrial, business, and residential installations.[¹][²] Terms such as "predictive" or "planned" maintenance describe various cost-effective practices aimed at keeping equipment operational; these activities occur either before[³] or after a potential failure.

Definitions

[edit]

Maintenance functions can be defined as **maintenance**, **repair and overhaul** (**MRO**), and MRO is also used for **maintenance**, **repair and operations**.[⁴] Over time, the terminology of maintenance and MRO has begun to become standardized. The United States Department of Defense uses the following definitions:[⁵]

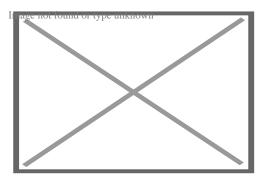

- Any activity—such as tests, measurements, replacements, adjustments, and repairs—intended to retain or restore a functional unit in or to a specified state in which the unit can perform its required functions.[⁵]
- All action taken to retain material in a serviceable condition or to restore it to serviceability. It includes inspections, testing, servicing, classification as to serviceability, repair, rebuilding, and reclamation.⁵
- All supply and repair action taken to keep a force in condition to carry out its mission.[⁵]
- The routine recurring work required to keep a facility (plant, building, structure, ground facility, utility system, or other real property) in such condition that it may be continuously used, at its original or designed capacity and efficiency for its intended purpose.[⁵]

Maintenance is strictly connected to the utilization stage of the product or technical system, in which the concept of maintainability must be included. In this scenario, maintainability is considered as the ability of an item, under stated conditions of use, to be retained in or restored to a state in which it can perform its required functions, using prescribed procedures and resources.[⁶]

In some domains like aircraft maintenance, terms *maintenance, repair and overhaul*⁷] also include inspection, rebuilding, alteration and the supply of spare parts, accessories, raw materials, adhesives, sealants, coatings and consumables for aircraft maintenance at the utilization stage. In international civil aviation maintenance means:

The performance of tasks required to ensure the continuing airworthiness of an aircraft, including any one or combination of overhaul, inspection, replacement, defect rectification, and the embodiment of a modification or a repair.⁸

This definition covers all activities for which aviation regulations require issuance of a maintenance release document (aircraft certificate of return to service – CRS).

Road repair

Types

[edit]

The marine and air transportation,[⁹] offshore structures,[¹⁰] industrial plant and facility management industries depend on *maintenance, repair and overhaul* (MRO) including scheduled or preventive paint maintenance programmes to maintain and restore coatings applied to steel in environments subject to attack from

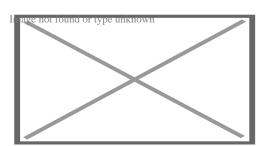

The basic types of maintenance falling under MRO include:

- Preventive maintenance, where equipment is checked and serviced in a planned manner (in a scheduled points in time or continuously)
- Corrective maintenance, where equipment is repaired or replaced after wear, malfunction or break down
- Reinforcement[¹¹]

Architectural conservation employs MRO to preserve, rehabilitate, restore, or reconstruct historical structures with stone, brick, glass, metal, and wood which match the original constituent materials where possible, or with suitable polymer technologies when not.[¹²]

Preventive maintenance

[edit]

C-130J Hercules preventive cleaning at Keesler Air Force Base, Mississippi after a period of operation over the Gulf of Mexico (salt and moisture which lead to active corrosion require regular cleaning)

Preventive maintenance (**PM**) is "a routine for periodically inspecting" with the goal of "noticing small problems and fixing them before major ones develop." $[^{13}]$ Ideally, "nothing breaks down." $[^{14}]$

The main goal behind PM is for the equipment to make it from one planned service to the next planned service without any failures caused by fatigue, extreme fluctuation in temperature(such as heat waves[¹⁵]) during seasonal changes, neglect, or normal wear (preventable items), which Planned Maintenance and Condition Based Maintenance help to achieve by replacing worn components before they actually fail. Maintenance activities include partial or complete overhauls at specified periods, oil changes, lubrication, minor adjustments, and so on. In addition, workers can record equipment deterioration so they know to replace or repair worn parts before they cause system failure.

The New York Times gave an example of "machinery that is not lubricated on schedule" that functions "until a bearing burns out." Preventive maintenance contracts are generally a fixed cost, whereas improper maintenance introduces a variable cost: replacement of major equipment.[¹³]

Main objective of PM are:

- 1. Enhance capital equipment productive life.
- 2. Reduce critical equipment breakdown.
- 3. Minimize production loss due to equipment failures.

Preventive maintenance or **preventative**[¹⁶] **maintenance** (**PM**) has the following meanings:

 The care and servicing by personnel for the purpose of maintaining equipment in satisfactory operating condition by providing for systematic inspection, detection, and correction of incipient failures either before they occur or before they develop into major defects.

- The work carried out on equipment in order to avoid its breakdown or malfunction. It is a regular and routine action taken on equipment in order to prevent its breakdown.[¹⁷]
- Maintenance, including tests, measurements, adjustments, parts replacement, and cleaning, performed specifically to prevent faults from occurring.

Other terms and abbreviations related to PM are:

- scheduled maintenance[¹⁸]
- planned maintenance,[¹⁹] which may include scheduled downtime for equipment replacement
- $_{\circ}\,$ planned preventive maintenance (PPM) is another name for PM[20]
- breakdown maintenance:[²⁰] fixing things only when they break. This is also known as "a reactive maintenance strategy"[²¹] and may involve "consequential damage."[²²]

Planned maintenance

[edit]

"Routine maintenance" redirects here. For the album by Aaron West and the Roaring Twenties, see Routine Maintenance (album).

Planned preventive maintenance (PPM), more commonly referred to as simply **planned maintenance (PM)** or **scheduled maintenance**, is any variety of scheduled maintenance to an object or item of equipment. Specifically, planned maintenance is a scheduled service visit carried out by a competent and suitable agent, to ensure that an item of equipment is operating correctly and to therefore avoid any unscheduled breakdown and downtime.[²³] The key factor as to when and why this work is being done is timing, and involves a service, resource or facility being unavailable.[¹⁸][¹⁹] By contrast, condition-based maintenance is not directly based on equipment age.

Planned maintenance is preplanned, and can be date-based, based on equipment running hours, or on distance travelled.

Parts that have scheduled maintenance at fixed intervals, usually due to wearout or a fixed shelf life, are sometimes known as time-change interval, or TCI items.

Predictive maintenance

[edit]

Main article: Predictive maintenance

Predictive maintenance techniques are designed to help determine the condition of in-service equipment in order to estimate when maintenance should be performed. This approach promises cost savings over routine or time-based preventive maintenance, because tasks are performed only when warranted. Thus, it is regarded as condition-based maintenance carried out as suggested by estimations of the degradation state of an item. The main promise of predictive maintenance is to allow convenient scheduling of corrective maintenance, and to prevent unexpected equipment failures.^[3] This maintenance strategy uses sensors to monitor key parameters within a machine or system, and uses this data in conjunction with analysed historical trends to continuously evaluate the system health and predict a breakdown before it happens.^[24] This strategy allows maintenance to be performed more efficiently, since more up-to-date data is obtained about how close the product is to failure.^[25]

Predictive replacement is the replacement of an item that is still functioning properly.^[26] Usually it is a tax-benefit based [[]*citation needed*[]] replacement policy whereby expensive equipment or batches of individually inexpensive supply items are removed and donated on a predicted/fixed shelf life schedule. These items are given to tax-exempt institutions.^[27] *[citation needed*[]]

Condition-based maintenance

[edit]

Condition-based maintenance (CBM), shortly described, is maintenance when need arises. Albeit chronologically much older, It is considered one section or practice inside the broader and newer predictive maintenance field, where new AI technologies and connectivity abilities are put to action and where the acronym CBM is more often used to describe 'condition Based Monitoring' rather than the maintenance itself. CBM maintenance is performed after one or more indicators show that equipment is going to fail or that equipment performance is deteriorating.

This concept is applicable to mission-critical systems that incorporate active redundancy and fault reporting. It is also applicable to non-mission critical systems that lack redundancy and fault reporting.

Condition-based maintenance was introduced to try to maintain the correct equipment at the right time. CBM is based on using real-time data to prioritize and optimize maintenance resources. Observing the state of the system is known as condition monitoring. Such a system will determine the equipment's health, and act only when maintenance is actually necessary. Developments in recent years have allowed extensive instrumentation of equipment, and together with better tools for analyzing condition data, the maintenance personnel of today is more than ever able to decide what is the right time to perform maintenance on some piece of equipment. Ideally, condition-based maintenance will allow the maintenance personnel to do only the right things, minimizing spare parts cost, system downtime and time spent on maintenance.

Challenges

[edit]

Despite its usefulness of equipment, there are several challenges to the use of CBM. First and most important of all, the initial cost of CBM can be high. It requires improved instrumentation of the equipment. Often the cost of sufficient instruments can be quite large, especially on equipment that is already installed. Wireless systems have reduced the initial cost. Therefore, it is important for the installer to decide the importance of the investment before adding CBM to all equipment. A result of this cost is that the first generation of CBM in the oil and gas industry has only focused on vibration in heavy rotating equipment.

Secondly, introducing CBM will invoke a major change in how maintenance is performed, and potentially to the whole maintenance organization in a company. Organizational changes are in general difficult.

Also, the technical side of it is not always as simple. Even if some types of equipment can easily be observed by measuring simple values such as vibration (displacement, velocity or acceleration), temperature or pressure, it is not trivial to turn this measured data into actionable knowledge about the health of the equipment.

Value potential

[edit]

As systems get more costly, and instrumentation and information systems tend to become cheaper and more reliable, CBM becomes an important tool for running a plant or factory in an optimal manner. Better operations will lead to lower production cost and lower use of resources. And lower use of resources may be one of the most important differentiators in a future where environmental issues become more important by the day.

Another scenario where value can be created is by monitoring the health of a car motor. Rather than changing parts at predefined intervals, the car itself can tell you when something needs to be changed based on cheap and simple instrumentation.

It is Department of Defense policy that condition-based maintenance (CBM) be "implemented to improve maintenance agility and responsiveness, increase operational availability, and reduce life cycle total ownership costs".[²⁸]

Advantages and disadvantages

[edit]

CBM has some advantages over planned maintenance:

- Improved system reliability
- Decreased maintenance costs

 Decreased number of maintenance operations causes a reduction of human error influences

Its disadvantages are:

- High installation costs, for minor equipment items often more than the value of the equipment
- Unpredictable maintenance periods cause costs to be divided unequally.
- Increased number of parts (the CBM installation itself) that need maintenance and checking.

Today, due to its costs, CBM is not used for less important parts of machinery despite obvious advantages. However it can be found everywhere where increased safety is required, and in future will be applied even more widely.[²⁹][³⁰]

Corrective maintenance

[edit]

Main article: Corrective maintenance

Corrective maintenance is a type of maintenance used for equipment after equipment break down or malfunction is often most expensive – not only can worn equipment damage other parts and cause multiple damage, but consequential repair and replacement costs and loss of revenues due to down time during overhaul can be significant. Rebuilding and resurfacing of equipment and infrastructure damaged by erosion and corrosion as part of corrective or preventive maintenance programmes involves conventional processes such as welding and metal flame spraying, as well as engineered solutions with thermoset polymeric materials.[³¹]

About Torsion spring

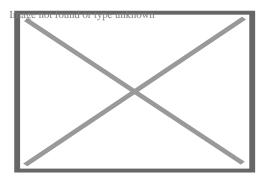

A torsion springtime is a spring that functions by twisting its end along its axis; that is, a versatile elastic object that shops power when it is twisted. When it is twisted, it exerts a torque in the contrary direction, symmetrical to the amount (angle) it is twisted. There are different kinds: A torsion bar is a straight bar of steel or rubber that undergoes turning (shear stress and anxiety) about its axis by torque applied at its ends. An even more delicate form utilized in sensitive instruments, called a torsion fiber includes a fiber of silk, glass, or quartz under tension, that is turned regarding its axis. A helical torsion springtime, is a metal rod or cord in the form of a helix (coil) that goes through twisting concerning the axis of the coil by sideways forces (flexing moments) applied to its ends, turning the coil tighter. Clocks make use of a spiral injury torsion springtime (a kind of helical torsion springtime where the coils are around each other instead of accumulated) often called a "clock springtime" or informally called a mainspring. Those kinds of torsion springs are additionally made use of for attic room stairs, clutches, typewriters and other devices that require near constant torque for huge angles or even multiple transformations.

About Coil spring

A coil spring is a mechanical tool that usually is utilized to store power and subsequently launch it, to take in shock, or to keep a pressure between calling surfaces. It is made of a flexible product created right into the form of a helix that returns to its all-natural length when unloaded. Under tension or compression, the material (wire) of a coil springtime undergoes torsion. The springtime characteristics therefore depend upon the shear modulus. A coil springtime might also be made use of as a torsion springtime: in this instance the spring all at once is subjected to torsion regarding its helical axis. The product of the springtime is thereby subjected to a flexing moment, either decreasing or boosting the helical span. In this mode, it is the Youthful's modulus of the product that figures out the spring characteristics.

Petersburg, Russia

Garage - in the style of the new objectivity - Frankfurt am Main

A 1901 newspaper article discussing a name for a private collection of automobiles

Image not found or type unknown

A 1901 newspaper article discussing a name for a private collection of automobiles, which mentions the word "garage" as being a possible choice except that that word was already in use in the broader sense of a place to store and repair them. Today the word *garage* has both senses; for example, *Jay Leno's Garage* is a series about his collection and other interesting collections, not merely the buildings that contain them.

A residential **garage** (UK: /Ã⊠â€'Ëâ€Ã⊠‰Ã,œrÃ⊠‰Ã¢â,¬ËœÃ⊠â€'ÃÃÃMŠââ,¬â,¢ -rÃ⊠‰Ã¢â,¬ËœÃ⊠â€'ÃÃÃMŠââ,¬â,¢ -rÃ⊠‰Ã,ÂđÃ⊠Šââ,¬â,¢ GARR-ahzh, -

$\tilde{A}f\hat{A}\phi\tilde{A},\hat{A}\bullet\tilde{A},\hat{A}$ ahj, - $\tilde{A}f\hat{A}\phi\tilde{A},\hat{A}\bullet\tilde{A},\hat{A},$ ij

Some garages have an electrical mechanism to automatically open or close the garage door when the homeowner presses a button on a small remote control, along with a detector that stops the movement of the garage if something is in the way of closing. Some garages have enough space, even with cars inside, for the storage of items such as bicycles or a lawnmower; in some cases, there may even be enough space for a workshop or a man cave. Garages that are attached to a house may be built with the same external materials and roofing as the house. Garages that are not connected to the home may use a different style of construction from the house. Often in the Southern and rural United States garages not attached to the home and made from a timber frame with sheet metal

coverings are known as "pole barns", but usually serve the same purpose as what is called a garage elsewhere. In some places, the term is used synonymously with "carport", though that term normally describes a structure that, while roofed, is not completely enclosed. A carport protects the vehicle to some degree from inclement weather, but it does not protect the vehicle from theft or vandalism.

The word *garage*, introduced to English in 1902, originates from the French word *garer*, meaning shelter.^[1] By 1908 the architect Charles Harrison Townsend was commenting in *The Builder* magazine that "for the home of the car, we very largely use the French word 'garage', alternatively with what I think the more desirable English equivalent of 'motor house'".^[2] Today the word is polysemic because it can refer to a collection of vehicles as well as the building that contains them.

Residential garage insulation

[edit]

In northern climates, temperatures inside an uninsulated attached residential garage can decrease to freezing levels during the winter. Temperatures inside an uninsulated attached garage in temperate climates can reach uncomfortable levels during summer months. Extreme temperatures can be a source of energy waste and discomfort in adjoining living areas, due to heat transfer between the garage and those areas. Homes with an attached garage often experience this "interface" problem. Insulating the outside of the building against the elements without extending the insulation to the wall separating the garage from the house, and/or the other garage walls and roof, can be a costly mistake.[³]

In Australia

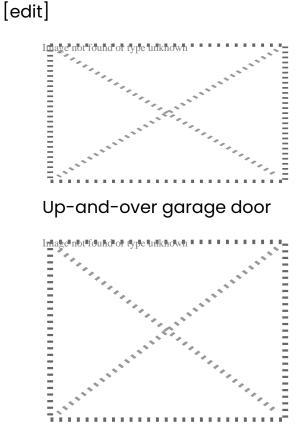

[edit]

Australian homes typically have a two, one and a half or double car garage, with some newer houses having a triple garage, with one double door and one single door. Prior to the 1970s most of them were detached from the house, usually set further back with the driveway leading up past the side of the house, common with old fibreboard houses, but not uncommon with earlier brick houses. The most common doors on these garages were either two wooden barn style doors with a standard sized access door on the side of the garage or the B&D Rolla Door, which is described below.

The most common garage door to date in Australia is the B&D Rolla Door, having been around since 1956 and still in heavy use today. They are a corrugated flexible but strong sheet steel door, sliding up tracks and rolling around a drum mounted above the door opening on the inside of the garage. These come in manual and remote controlled electric (known as the Control-a-Door), with conversion kits available. Locking is provided by a key lock in the centre of the door moving two square sliding lock bars in and out of holes in the door tracks, locking and unlocking it, or by the solenoid lock in the automatic motor.

Newer homes feature more American styled tilting panel lift doors which slide up onto a track on the ceiling via a motor and chain drive. Since the late 1970s most if not all garages are attached, and throughout the 80's it became more common to have an access door into the home from the garage where design permitted, whereas it is commonplace now. Most older unit (apartment) blocks in Australia have garages on the ground floor accessible through a common hallway and access doors, all leading into a common driveway. Newer ones now have underground parking. Australia has strict guidelines in place when building a home and the garage size must conform to the Australian Standards. The minimum size for a single garage is $3.0 \text{ m} \times 5.4 \text{ m} (9.8 \text{ ft} \times 17.7 \text{ ft})$ and a double is $5.4 \text{ m} \times 5.4 \text{ m} (17.7 \text{ ft} \times 17.7 \text{ ft})$. However, to comfortably fit two cars in a double garage it is typical to have a size of $6.0 \text{ m} \times 6.0 \text{ m} (19.7 \text{ ft} \times 19.7 \text{ ft})$.

In the United Kingdom

Insulation of sectional garage door

British homes featuring a garage typically have a single or double garage either built into the main building, detached within the grounds (often in the back garden), or in a communal area.

Traditionally, garage doors were wooden, opening either as two leaves or sliding horizontally. Newer garages are fitted with metal up-and-over doors. Increasingly,

in new homes, such doors are electrically operated.

Typically, a small British single garage is 8 by 16 feet ($2.4 \text{ m} \times 4.9 \text{ m}$), a medium single garage is 9 by 18 feet ($2.7 \text{ m} \times 5.5 \text{ m}$), and a large single garage is 10 by 20 feet ($3.0 \text{ m} \times 6.1 \text{ m}$). Family sedans have become bigger than they were in the past, so the larger size has become a preferred option. A typical large family car like the Ford Mondeo is about 15 by 6 feet ($4.6 \text{ m} \times 1.8 \text{ m}$), meaning that even with the larger size garage, it is necessary to park to one side to be able to open the driver's door wide enough to enter or exit the vehicle.

In the early days of the motor car, a garage played an important role in protecting the vehicle from the weather (particularly so as to reduce rust). It was also the case that early motor cars started more easily when they were warm,[⁵] so that keeping them in a garage rather than outside made it easier to get the engine going in the morning. Modern motor cars, however, are very well protected against rust, and modern engines start with no difficulty even in very cold conditions.

Early history

[edit]

The common term for these structures in the first decades of the 20th century was motor house. Many garages from before 1914 were pre-fabricated, typically by companies such as Norwich manufacturer Boulton & Paul Ltd. The style was usually in keeping with that of the house and its locale, however, they were mainly of timber construction and few have survived.[⁶]

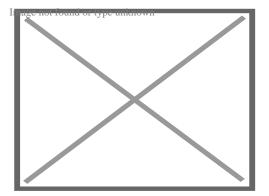

E. Keynes Purchase, "honorary architect" to what was to become the Royal Automobile Club, did a lot of work on them and recommended in *The Car Illustrated* in 1902, that they be of brick construction with cement floor, an inspection pit, good electric lighting and a pulley system for removing parts of the car (in the early days of motoring many car owners were mechanical and engineering enthusiasts).[⁷]

The architecture of garages was ignored in the architectural journals despite famous architects such as Edwin Lutyens, Richard Barry Parker and Edgar Wood all designing garages for their wealthy clients. Charles Harrison Townsend was one of the few architects who put pen to paper (in *The Builder* in 1908) on the subject and recommended that the walls be glazed brick for ease of washing, air gratings to be low (petrol fumes are heavier than air), and drains half open to avoid build-up of gases.[⁸]

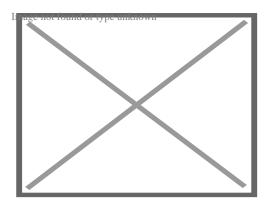

By 1910 corrugated iron and asbestos were being used instead of wood and garages became less imposing. From 1912 speculatively built houses in London were being built with motor houses.[⁹]

In North America

[edit]

Mobile homes with detached single car garages

Circa 1955 detached residential garage seen in Toledo, Ohio

Many garage doors open upward using an electric chain drive, which can often be automatically controlled from inside the resident's vehicle with a small radio transmitter.[¹⁰] Garages are connected to the nearest road with a driveway. Interior space for one or two cars is normal, and garages built after 1950 usually have a door that connects the garage directly to the interior of the house (an "attached garage"). Earlier garages were often detached and located in the back yard of the house, accessed either via a long driveway or from an alley.

In the past, garages were often separate buildings from the house ("detached garage"). On occasion, a garage would be built with an apartment above it, which could be rented out. As automobiles became more popular, the concept of attaching the garage directly to the home grew into a common practice. While a person with a separate garage must walk outdoors in every type of weather, a person with an attached garage has a much shorter walk inside a building.

Around the start of the 21st century, companies began offering "portable garages" in the United States. Typically, these garages are made of metal, wood or vinyl and do not connect to the house or other structure, much like the garage built before 1950. This portable garages usually have a strongly reinforced floor to hold a heavy vehicle. Garages are also produced as composite fabric garages with metal frames that are lightweight and portable garage compared to traditional brick-andOver the past fifteen years, the portable garage has further evolved into a modular garage or a partially prefabricated structure. The modular garage comes from a factory that assembles the garage in two sections and combines the two sections on location. Partially prefabricated garages are often larger and might even include an attic space or a second floor. Sections of the garage are preassembled and then setup on site over a few days time.[¹²] The Amish have become popular builders of portable, modular and partially prefabricated garages.

Common Garage Sizes in the United States

[edit]

Garage sizes in the United States vary depending on the number of vehicles they are designed to accommodate. While dimensions can differ based on specific needs and local building codes, typical sizes are as follows:

- One-car garage: Usually 12 to 18 feet wide and 20 to 30 feet deep, with a total area of 240 to 540 square feet.
- Two-car garage: Commonly 20 to 24 feet wide, maintaining the same depth, and covering 360 to 660 square feet.
- Three-car garage: Typically 30 to 36 feet wide, providing 600 to 1,260 square feet of space.
- Four-car garage: The largest standard size, ranging from 40 to 48 feet wide, with a total area of 800 to 1,600 square feet.

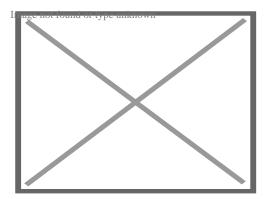

These dimensions offer enough space not only for vehicles but also for storage and accessibility. Garage sizes may vary depending on design preferences, vehicle

types, and additional space requirements.^{[13}]

Post frame garages

[edit]

Post frame garage attached to traditional frame house

Often in more rural settings, detached post-frame garages are used to store farm and workshop equipment and can either be cold storage[¹⁴] or insulated for warm storage.[¹⁵][¹⁶]

Notable garages

[edit]

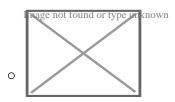

The first planned private garages appeared long before 1900. Early examples of planned public garages appeared at the same time. The first recorded public parking garage in the US (*Electric Vehicle Company Garage*,[¹⁷] Chicago) was built in 1898, in the UK (*Christal Palace Garage*,[¹⁸] London) in 1900 and in Germany (*Großgarage der Automüller G.m.b.H.*,[¹⁹] Berlin-Wilmersdorf) in 1901.

Possibly the oldest existing garage in the United Kingdom is in Southport Lancashire. It was the first motor house or garage to be depicted in an English motoring journal and was in The Autocar of 7 October 1899. It was owned by Dr W.W. Barratt, a local doctor and motoring pioneer and specially designed for his house at 29 Park Crescent Hesketh Park. A two-storey building that matched the style of the house; the ground floor garage having a concrete floor, heating, electric lighting, an engine pit and was fully equipped. The motor house is now in residential use.[²⁰]

One of the oldest surviving private garages in Germany today is the 1903 finished *Automobil-Remise* (automobile carriage house) of Villa Esche by Henry van de Velde in Chemnitz. Carl Benz, the inventor of the automobile, had a tower built for himself in 1910, on the first floor a room for studying, on the ground floor car parking space. It still exists in Ladenburg, Germany.

Carhouses

[edit]

Garages in the United States and Canada used to store streetcars and buses are often referred to as carhouses or car barns. These storage facilities are either metal or brick structures used to store streetcars or buses away from the elements. In Britain they are referred to as bus depots or depots.

About Spring (device)

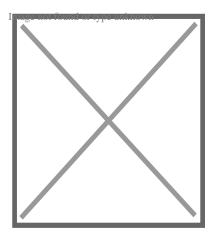

Helical coil springs designed for tension

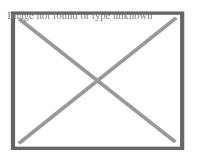

A heavy-duty coil spring designed for compression and tension

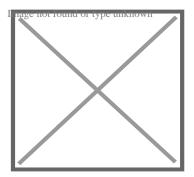

The English longbow – a simple but very powerful spring made of yew, measuring 2 m (6 ft 7 in) long, with a 470 N (105 lbf) draw weight, with each limb functionally a cantilever spring.

Force (F) vs extension (s).[[]*citation needed*[]] Spring characteristics: (1) progressive, (2) linear, (3) degressive, (4) almost constant, (5) progressive with knee

A machined spring incorporates several features into one piece of bar stock

Military booby trap firing device from USSR (normally connected to a tripwire) showing spring-loaded firing pin

A **spring** is a device consisting of an elastic but largely rigid material (typically metal) bent or molded into a form (especially a coil) that can return into shape after being compressed or extended.^[1] Springs can store energy when compressed. In everyday use, the term most often refers to coil springs, but there are many different spring designs. Modern springs are typically manufactured from spring steel. An example of a non-metallic spring is the bow, made traditionally of flexible yew wood, which when drawn stores energy to propel an arrow.

When a conventional spring, without stiffness variability features, is compressed or stretched from its resting position, it exerts an opposing force approximately

proportional to its change in length (this approximation breaks down for larger deflections). The *rate* or *spring constant* of a spring is the change in the force it exerts, divided by the change in deflection of the spring. That is, it is the gradient of the force versus deflection curve. An extension or compression spring's rate is expressed in units of force divided by distance, for example or N/m or lbf/in. A torsion spring is a spring that works by twisting; when it is twisted about its axis by an angle, it produces a torque proportional to the angle. A torsion spring's rate is in units of torque divided by angle, such as N·m/rad or ft·lbf/degree. The inverse of spring rate is compliance, that is: if a spring has a rate of 10 N/mm, it has a compliance of 0.1 mm/N. The stiffness (or rate) of springs in parallel is additive, as is the compliance of springs in series.

Springs are made from a variety of elastic materials, the most common being spring steel. Small springs can be wound from pre-hardened stock, while larger ones are made from annealed steel and hardened after manufacture. Some nonferrous metals are also used, including phosphor bronze and titanium for parts requiring corrosion resistance, and low-resistance beryllium copper for springs carrying electric current.

History

[edit]

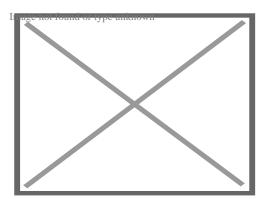

Simple non-coiled springs have been used throughout human history, e.g. the bow (and arrow). In the Bronze Age more sophisticated spring devices were used, as shown by the spread of tweezers in many cultures. Ctesibius of Alexandria developed a method for making springs out of an alloy of bronze with an increased proportion of tin, hardened by hammering after it was cast. Coiled springs appeared early in the 15th century,[²] in door locks.[³] The first spring powered-clocks appeared in that century[³][⁴][⁵] and evolved into the first large watches by the 16th century.

In 1676 British physicist Robert Hooke postulated Hooke's law, which states that the force a spring exerts is proportional to its extension.

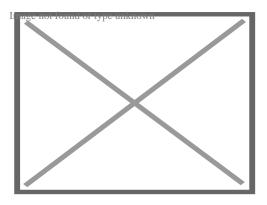

On March 8, 1850, John Evans, Founder of John Evans' Sons, Incorporated, opened his business in New Haven, Connecticut, manufacturing flat springs for carriages and other vehicles, as well as the machinery to manufacture the springs. Evans was a Welsh blacksmith and springmaker who emigrated to the United States in 1847, John Evans' Sons became "America's oldest springmaker" which continues to operate today.[⁶]

Types

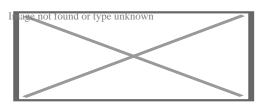

[edit]

A spiral torsion spring, or hairspring, in an alarm clock.

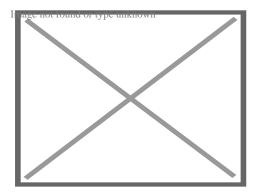

Battery contacts often have a variable spring

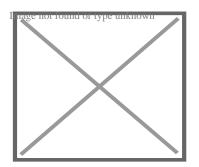

A volute spring. Under compression the coils slide over each other, so

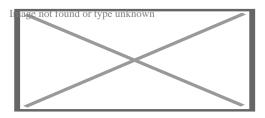

affording longer travel.

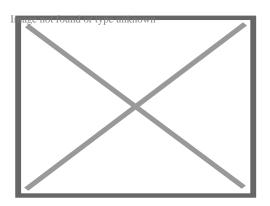

Vertical volute springs of Stuart tank

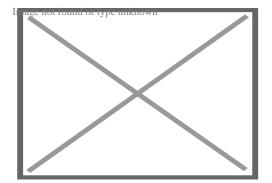

Selection of various arc springs and arc spring systems (systems consisting of inner and outer arc springs).

Tension springs in a folded line reverberation device.

A torsion bar twisted under load

Leaf spring on a truck

Classification

[edit]

Springs can be classified depending on how the load force is applied to them:

Tension/extension spring

The spring is designed to operate with a tension load, so the spring stretches as the load is applied to it.

Compression spring

Designed to operate with a compression load, so the spring gets shorter as the load is applied to it.

Torsion spring

Unlike the above types in which the load is an axial force, the load applied to a torsion spring is a torque or twisting force, and the end of the spring rotates through an angle as the load is applied.

Constant spring

Supported load remains the same throughout deflection cycle[[']]

Variable spring

Resistance of the coil to load varies during compression[⁸]

Variable stiffness spring

Resistance of the coil to load can be dynamically varied for example by the control system, some types of these springs also vary their length thereby providing actuation capability as well [9]

They can also be classified based on their shape:

Flat spring

Made of a flat spring steel.

Machined spring

Manufactured by machining bar stock with a lathe and/or milling operation rather than a coiling operation. Since it is machined, the spring may

incorporate features in addition to the elastic element. Machined springs can

be made in the typical load cases of compression/extension, torsion, etc.

Serpentine spring

A zig-zag of thick wire, often used in modern upholstery/furniture. Garter spring A coiled steel spring that is connected at each end to create a circular shape.

Common types

[edit]

The most common types of spring are:

Cantilever spring

A flat spring fixed only at one end like a cantilever, while the free-hanging end takes the load.

Coil spring

Also known as a helical spring. A spring (made by winding a wire around a cylinder) is of two types:

- Tension or extension springs are designed to become longer under load. Their turns (loops) are normally touching in the unloaded position, and they have a hook, eye or some other means of attachment at each end.
- Compression springs are designed to become shorter when loaded. Their turns (loops) are not touching in the unloaded position, and they need no attachment points.
- Hollow tubing springs can be either extension springs or compression springs.
 Hollow tubing is filled with oil and the means of changing hydrostatic pressure inside the tubing such as a membrane or miniature piston etc. to harden or relax the spring, much like it happens with water pressure inside a garden hose.
 Alternatively tubing's cross-section is chosen of a shape that it changes its area when tubing is subjected to torsional deformation: change of the cross-section area translates into change of tubing's inside volume and the flow of oil in/out of the spring that can be controlled by valve thereby controlling

stiffness. There are many other designs of springs of hollow tubing which can change stiffness with any desired frequency, change stiffness by a multiple or move like a linear actuator in addition to its spring qualities.

Arc spring

A pre-curved or arc-shaped helical compression spring, which is able to transmit a torque around an axis.

Volute spring

A compression coil spring in the form of a cone so that under compression the coils are not forced against each other, thus permitting longer travel.

Balance spring

Also known as a hairspring. A delicate spiral spring used in watches,

galvanometers, and places where electricity must be carried to partially

rotating devices such as steering wheels without hindering the rotation.

Leaf spring

A flat spring used in vehicle suspensions, electrical switches, and bows.

V-spring

Used in antique firearm mechanisms such as the wheellock, flintlock and percussion cap locks. Also door-lock spring, as used in antique door latch mechanisms.[¹⁰]

Other types

[edit]

Other types include:

Belleville washer

A disc shaped spring commonly used to apply tension to a bolt (and also in

the initiation mechanism of pressure-activated landmines)

Constant-force spring

A tightly rolled ribbon that exerts a nearly constant force as it is unrolled Gas spring

A volume of compressed gas.

Ideal spring

An idealised perfect spring with no weight, mass, damping losses, or limits, a concept used in physics. The force an ideal spring would exert is exactly proportional to its extension or compression.[¹¹]

Mainspring

A spiral ribbon-shaped spring used as a power store of clockwork mechanisms: watches, clocks, music boxes, windup toys, and mechanically

powered flashlights

Negator spring

A thin metal band slightly concave in cross-section. When coiled it adopts a flat cross-section but when unrolled it returns to its former curve, thus producing a constant force throughout the displacement and *negating* any tendency to re-wind. The most common application is the retracting steel tape rule.[¹²]

Progressive rate coil springs

A coil spring with a variable rate, usually achieved by having unequal distance between turns so that as the spring is compressed one or more coils rests against its neighbour.

Rubber band

A tension spring where energy is stored by stretching the material. Spring washer Used to apply a constant tensile force along the axis of a fastener.

Torsion spring

Any spring designed to be twisted rather than compressed or extended.¹³ Used in torsion bar vehicle suspension systems.

Wave spring

various types of spring made compact by using waves to give a spring effect.

Main article: Wave spring

Physics

[edit]

Hooke's law

[edit]

Main article: Hooke's law

An ideal spring acts in accordance with Hooke's law, which states that the force with which the spring pushes back is linearly proportional to the distance from its equilibrium length:

holisptaystyle Fernkkxwn

where

is the displacement vector – the distance from its equilibrium length. Adsplaystyle x is the resulting force vector – the magnitude and direction of the restoring force the spring exerts

is the **rate, spring constant** or **force constant** of the spring, a constant that depends on the spring's material and construction. The negative sign indicates that the force the spring exerts is in the opposite direction from its displacement

Most real springs approximately follow Hooke's law if not stretched or compressed beyond their elastic limit.

Coil springs and other common springs typically obey Hooke's law. There are useful springs that don't: springs based on beam bending can for example produce forces that vary nonlinearly with displacement.

If made with constant pitch (wire thickness), conical springs have a variable rate. However, a conical spring can be made to have a constant rate by creating the spring with a variable pitch. A larger pitch in the larger-diameter coils and a smaller pitch in the smaller-diameter coils forces the spring to collapse or extend all the coils at the same rate when deformed.

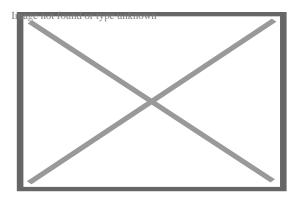

Simple harmonic motion

[edit]

Main article: Harmonic oscillator

Since force is equal to mass, *m*, times acceleration, *a*, the force equation for a spring obeying Hooke's law looks like:

haisplaystyle remand \Rightarrow \quad -kx=ma.\,

The displacement, *x*, as a function of time. The amount of time that passes between peaks is called the period.

The mass of the spring is small in comparison to the mass of the attached mass and is ignored. Since acceleration is simply the second derivative of x with respect to time,

Image not found or type unknown

This is a second order linear differential equation for the displacement and so a found of type unkn \displaystyle x

```
\displaystyle \frac d^2xdt^2+\frac kmx=0,\,
```

Image not found or type unknown

the solution of which is the sum of a sine and cosine:

```
\displaystyle x(t)=A\sin \left(t\sqrt \frac km\right)+B\cos \left(t\sqrt \frac km\right)
```

Image not found or type unknown

and are arbitrary constants that may be found by considering the initial displayed style B and velocity of the mass. The graph of this function with displayed in the image on the initial position with some positive initial velocity) is displayed in the image on the right.

Energy dynamics

[edit]

In simple harmonic motion of a spring-mass system, energy will fluctuate between kinetic energy and potential energy, but the total energy of the system remains the same. A spring that obeys Hooke's law with spring constant *k* will have a total system energy *E* of:[¹⁴]

```
\displaystyle E=\left(\frac 12\right)kA^2
```

Image not found or type unknown

Here, A is the amplitude of the wave-like motion that is produced by the oscillating behavior of the spring.

The potential energy U of such a system can be determined through the spring constant k and its displacement $x [^{14}]$

\displaystyle U=\left(\frac 12\right)kx^2

Image not found or type unknown

The kinetic energy K of an object in simple harmonic motion can be found using the mass of the attached object m and the velocity at which the object oscillates v.[¹⁴]

\displaystyle K=\left(\frac 12\right)mv^2

Image not found or type unknown

Since there is no energy loss in such a system, energy is always conserved and thus:[¹⁴]

haisplaystylerE=K+Un

Frequency & period

[edit]

The angular frequency \boxtimes of an object in simple harmonic motion, given in radians per second, is found using the spring constant *k* and the mass of the oscillating object $m[^{15}]$:

\displaystyle \omega = \sqrt \frac km Image not found or type unknown

The period T, the amount of time for the spring-mass system to complete one full cycle, of such harmonic motion is given by:[16]

\displaystyle T=\frac 2\pi \omega =2\pi \sqrt \frac mk

The frequency *f*, the number of oscillations per unit time, of something in simple harmonic motion is found by taking the inverse of the period:[¹⁴]

Theory

[edit]

In classical physics, a spring can be seen as a device that stores potential energy, specifically elastic potential energy, by straining the bonds between the atoms of an elastic material.

Hooke's law of elasticity states that the extension of an elastic rod (its distended length minus its relaxed length) is linearly proportional to its tension, the force used

to stretch it. Similarly, the contraction (negative extension) is proportional to the compression (negative tension).

This law actually holds only approximately, and only when the deformation (extension or contraction) is small compared to the rod's overall length. For deformations beyond the elastic limit, atomic bonds get broken or rearranged, and a spring may snap, buckle, or permanently deform. Many materials have no clearly defined elastic limit, and Hooke's law can not be meaningfully applied to these materials. Moreover, for the superelastic materials, the linear relationship between force and displacement is appropriate only in the low-strain region.

Hooke's law is a mathematical consequence of the fact that the potential energy of the rod is a minimum when it has its relaxed length. Any smooth function of one variable approximates a quadratic function when examined near enough to its minimum point as can be seen by examining the Taylor series. Therefore, the force – which is the derivative of energy with respect to displacement – approximates a linear function.

The force of a fully compressed spring is:

```
\ F_max = \frac{1}{10} - \frac{1}{10} -
```

Image not found or type unknown

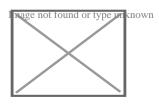

where

- E Young's modulus
- d spring wire diameter
- L free length of spring
- n number of active windings

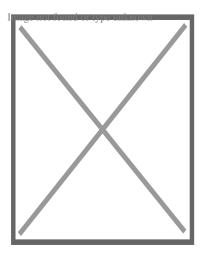

na Poisson ratio Naisplaystyle \nu D - spring outer diameter.

Zero-length springs

[edit]

Simplified LaCoste suspension using a zero-length spring

Spring length L vs force F graph of ordinary (+), zero-length (0) and negative-length (-) springs with the same minimum length L_0 and spring constant

Zero-length spring is a term for a specially designed coil spring that would exert zero force if it had zero length. That is, in a line graph of the spring's force versus its length, the line passes through the origin. A real coil spring will not contract to zero length because at some point the coils touch each other. "Length" here is defined as the distance between the axes of the pivots at each end of the spring, regardless of any inelastic portion in-between. Zero-length springs are made by manufacturing a coil spring with built-in tension (A twist is introduced into the wire as it is coiled during manufacture; this works because a coiled spring *unwinds* as it stretches), so if it *could* contract further, the equilibrium point of the spring, the point at which its restoring force is zero, occurs at a length of zero. In practice, the manufacture of springs is typically not accurate enough to produce springs with tension consistent enough for applications that use zero length springs, so they are made by combining a *negative length* spring, made with even more tension so its equilibrium point would be at a *negative* length, with a piece of inelastic material of the proper length so the zero force point would occur at zero length.

A zero-length spring can be attached to a mass on a hinged boom in such a way that the force on the mass is almost exactly balanced by the vertical component of the force from the spring, whatever the position of the boom. This creates a horizontal pendulum with very long oscillation period. Long-period pendulums enable seismometers to sense the slowest waves from earthquakes. The LaCoste suspension with zero-length springs is also used in gravimeters because it is very sensitive to changes in gravity. Springs for closing doors are often made to have roughly zero length, so that they exert force even when the door is almost closed, so they can hold it closed firmly.

Uses

[edit]

- Airsoft gun
- Aerospace

- Retractable ballpoint pens
- Buckling spring keyboards
- Clockwork clocks, watches, and other things
- Firearms
- Forward or aft spring, a method of mooring a vessel to a shore fixture
- Gravimeters
- Industrial Equipment
- Jewelry: Clasp mechanisms
- Most folding knives, and switchblades
- Lock mechanisms: Key-recognition and for coordinating the movements of various parts of the lock.
- Spring mattresses
- Medical Devices^{[17}]
- Pogo Stick
- Pop-open devices: CD players, tape recorders, toasters, etc.
- Spring reverb
- Toys; the Slinky toy is just a spring
- Trampoline
- Upholstery coil springs
- Vehicle suspension, Leaf springs

About Garage door

A garage door is a big door to allow access to a garage that opens either by hand or by an electrical motor (a garage door opener). Garage doors are often big enough to accommodate vehicles and other automobiles. The operating device is normally spring-loaded or counterbalanced to offset the door's weight and minimize the human or electric motor initiative called for to run the door. Less generally, some garage doors slide or swing horizontally. Doors are made from timber, metal, or fiberglass, and may be shielded to stop heat loss.

About Remote control

A remote control, also recognized colloquially as a remote or clicker, is a digital gadget made use of to run one more tool from a distance, typically wirelessly. In consumer electronics, a remote can be utilized to run gadgets such as a television set, DVD gamer or other digital home media appliance. A remote can permit operation of gadgets that run out hassle-free grab direct procedure of controls. They operate best when made use of from a brief range. This is mainly a convenience feature for the user. In some cases, remote controls enable an individual to operate a device that they or else would not have the ability to get to, as when a garage door opener is triggered from outside. Early tv remote controls (1956--- 1977) used ultrasonic tones. Contemporary push-button controls are frequently customer infrared tools which send digitally coded pulses of infrared radiation. They control functions such as power, volume, networks, playback, track change, energy, follower speed, and different other functions. Remote controls for these devices are typically small wireless handheld items with an array of buttons. They are made use of to change different setups such as television network, track

number, and quantity. The remote control code, and thus the needed remote control gadget, is generally particular to a product. Nevertheless, there are universal remotes, which imitate the remote created a lot of major brand name devices. Remote controls in the 2000s include Bluetooth or Wi-Fi connection, motion sensorenabled capabilities and voice control. Remotes for 2010s forward Smart TVs might include a standalone keyboard on the rear side to help with typing, and be useful as a pointing tool.

- Indiana county number 45
- Second most-populous county in Indiana

Lake County is a county located in the U.S. state of Indiana. In 2020, its population was 498,700,[⁹] making it Indiana's second-most populous county. The county seat is Crown Point.[¹⁰] The county is part of Northwest Indiana and the Chicago metropolitan area, and contains a mix of urban, suburban and rural areas. It is bordered on the north by Lake Michigan and contains a portion of the Indiana Dunes.[¹¹][¹²] It includes Marktown, Clayton Mark's planned worker community in East Chicago.[¹³]

History

[edit]

Early settlement

[edit]

Originally inhabited by the Potawatomi and generations of indigenous ancestors, Lake County was established by European Americans on February 16, 1837.^[2] From 1832 to 1836 the area that was to become Lake County was part of La Porte County. ¹⁴] From 1836 to 1837 it was part of Porter County.^[14] It was named for its location on Lake Michigan.^[15] The original county seat was Liverpool, but in 1840 Lake Court House, later renamed as Crown Point, was chosen.^{[16}]

Lake County's population grew slowly before the 1850s. Construction of railroads to link Chicago to the rest of the country stimulated rapid development, and tens of thousands of settlers and immigrants bought land in the region. Small-scale industrialization began, but was primarily relegated to the northern coast of the county, where it could take advantage of the railroads along the coast and shipping on the Great Lakes. The 1900 Census gives a population of 37,892 residents.

Industrialization and immigration

[edit]

Inland Steel Company established a plant in East Chicago in 1903 and U.S. Steel founded one in Gary in 1906; with industrial jobs the demand for labor associated with industrial jobs, the county's population exploded. Immigrants poured into the area from all over Central and Eastern Europe (there was also a smaller Mexican immigrant community). In addition, both black and white migrants came from many regions of the United States, particularly Appalachia and the South. Mostly rural blacks went north in the Great Migration, seeking both industrial jobs and escape from Jim Crow violence and disenfranchisement in the South.

By 1930, Lake County's population surpassed 260,000, with first- and secondgeneration Americans constituting a majority of the population. The second wave of the Ku Klux Klan gained a large following here in the 1920s, as it did for a time in the rest of Indiana. The KKK organized against the numerous European immigrants, who were mostly Catholic. While the steel industry reigned supreme, other industries also found the county to be an ideal location for cheap land and welldeveloped transportation networks, such as automobiles, oil, chemicals, consumer goods, food processing, and construction supply companies.[¹⁷]

The Great Depression was devastating to Lake County, as it was to other areas with economies based on heavy industry. The Depression, combined with industrial strife, changing demographics, and unionization, caused a realignment of politics in Lake County. It became a stronghold of the Democratic Party; Lake County has supported the Democratic nominee for president in every election since 1932 (exceptions occurred in 1956 and 1972). Indiana's 1st congressional district has elected Democratic candidates in every election since 1930.

World War II restored prosperity, as industry revived to support the war effort. Good economic times continued into the 1970s. During this period, unions helped industrial workers gain middle-class wages. In addition to attracting refugees and immigrants from Europe, black Americans and Mexicans migrated here in the postwar period in even higher numbers than in the 1910-1930 period. As minority populations exploded in such industrial cities as East Chicago and Gary, racial tensions surfaced again. Following construction of state and federal highways, development of cheaper land provided newer housing to middle-class people who could afford it. Both whites and established black families moved out of the aging industrial cities.[¹⁷]

Recent history

[edit]

Lake County's population peaked at 546,000 in 1970. Severe industrial decline took place during the 1973-1991 period, brought on by foreign competition, new

management philosophies that called for major workforce reductions, and productivity gains from technology. The decline was particularly intense in the steel industry: steel employment exceeded 60,000 in the 1960s, and declined progressively to just 18,000 by 2015. Lake County's population declined 13% to bottom out at 475,000 in 1990.

The industrial decline of the 1980s cast a long shadow over Lake County: the county did not regain the level of employment it had in 1980 until 1996, after which the employment level roughly flatlined. The county's economic output peaked in 1978, and has not since recovered, remaining 15–20% below the peak after adjusting for inflation. As prosperity declined, so did the immigration that powered the county's explosive population growth before 1950: per the 2000 census, only 5.3% of Lake County's residents were foreign-born, compared to over 11% for the United States as a whole.[¹⁸]

The population recovered somewhat during the 1990s and 2000s, as the local economy adjusted. Suburban growth has also been driven by commuter populations of workers who are employed in Chicago and commute via expressways or the South Shore Line. In 2007, it was estimated that 44,000 workers commuted from Lake County, Indiana, to Chicago for work.^[18] The decline of industrial cities and growth of suburbs has been so sharp, that by 1990 a majority of the county's population lived outside of the four traditional industrial cities. Lake County still continues to struggle with urban decline and poverty, suburban sprawl and traffic jams, and a stagnating population.^[17]

Geography

According to the 2010 census, the county has a total area of 626.56 square miles $(1,622.8 \text{ km}^2)$, of which 498.96 square miles $(1,292.3 \text{ km}^2)$ (or 79.63%) is land and 127.60 square miles (330.5 km^2) (or 20.37%) is water. It is the second-largest county in total area in Indiana, but has the largest water area of all 92 counties.[¹⁹]

The northern and southern portions of the county (north of U.S. 30 and south of Lowell) are mainly low and flat, except for a few sand ridges and dunes and were both once very marshy and had to be drained. The lowest point, at 585 feet (178 m), $[^7]$ is along the Lake Michigan shoreline.

The central part of the county is higher and hillier. As you travel south from the low and relatively flat lake plain in the northern part of the county, the land gradually rises in elevation until the peak of the Valparaiso Moraine. The highest point, at 801 feet (244 m),[⁶] is in northeastern Winfield Township near 109th Street and North Lakeshore Drive in Lakes of the Four Seasons. From here the land descends south into the Kankakee Outwash Plain until the Kankakee River is reached.

The geographic center of Lake County is approximately 200 feet (60 m) northwest of Burr Street and West 113th Avenue in Center Township

- Ross
- Southeast Grove

Townships

[edit]

The 11 townships of Lake County, with their populations as of the 2020 Census, are:

- Calumet 91,970
- Cedar Creek 12,725
- Center 38,630
- Eagle Creek 1,719
- Hanover 18,214
- Hobart 40,652
- North 156,686
- Ross 48,529
- St. John 68,972
- West Creek 7,676
- Winfield 12,927

Economy

[edit]

Despite the decline of heavy industry, manufacturing was still the largest employment sector in Lake County in 2010 with over 45,000 workers employed, followed closely by healthcare and social assistance at 44,000 workers, public administration at 40,000 workers, retail trade at 37,000 workers, accommodation and food services at 25,000 workers, and construction at 15,000 workers.[¹⁸]

Lake County's GDP in 2010 was measured at nearly \$25 billion. Manufacturing was also the largest sector of the economy in economic terms, contributing over \$5.8 billion to the county's GDP in 2010. It was followed by healthcare and social assistance at \$2.6 billion, public administration at \$2.5 billion, and retail trade at \$1.9 billion. While Lake County's average income was approximately 24% higher than the national average in 1978, in 2010 Lake County had fallen significantly behind the United States as a whole, with average income being approximately 12.9% lower. The national average surpassed Lake County sometime around 1986.

Businesses with the largest number of employees in the county are: $[^{20}]$

- Americall Group, Inc. Hobart
- Ameristar Casino East Chicago
- BP Whiting Refinery Whiting
- Canadian National Railway Whiting
- Cargill Hammond
- Cleveland-Cliffs Indiana Harbor Works East Chicago

- U.S. Steel Gary Works Gary

Education

[edit]

Public school districts

[edit]

The administration of public schools in Lake County is divided among 16 corporations and governing bodies,[²¹] more than any other Indiana county.[²²]

- Crown Point Community School Corporation Center and Winfield townships
- Gary Community School Corporation City of Gary
- Griffith Public Schools Town of Griffith
- Hanover Community School Corporation Hanover Township
- Lake Central School Corporation St. John Township
- Lake Ridge Schools Corporation unincorporated Calumet Township
- Lake Station Community Schools City of Lake Station
- Merrillville Community School Corporation Ross Township
- River Forest Community School Corporation Town of New Chicago and some portions of adjacent communities
- School City of East Chicago City of East Chicago
- School City of Hammond City of Hammond

- School City of Hobart City of Hobart within Hobart Township
- School City of Whiting City of Whiting
- School Town of Highland Town of Highland
- School Town of Munster Town of Munster
- Tri-Creek School Corporation Cedar Creek, Eagle Creek and West Creek townships

Private schools

[edit]

Elementary and secondary schools operated by the Diocese of Gary:

- Andrean High School, Merrillville (9–12)
- Aquinas School at St. Andrew's, Merrillville (PK-8)
- Bishop Noll Institute, Hammond (9–12)
- \circ Our Lady of Grace, Highland (PK-8)
- St. Casimir, Hammond (PK-8)
- St. John Bosco, Hammond (PK-8)
- \circ St. John the Baptist, Whiting (PK-8)
- \circ St. John the Evangelist, St. John (PK–8)
- St. Mary, Crown Point (PK-8)
- St. Mary, Griffith (PK-8)
- St. Michael, Schererville (PK-8)
- St. Stanislaus, East Chicago (PK-8)
- St. Thomas More, Munster (PK-8)

Other parochial and private schools:

- St. Paul's Lutheran School, Munster (PK-8)
- Trinity Lutheran School, Crown Point (PK-8)
- Trinity Lutheran School, Hobart (PK-8)

Colleges and universities

[edit]

- Calumet College of St. Joseph
- Hyles-Anderson College
- Indiana University Northwest
- Ivy Tech Community College
- Purdue University Northwest²³]
- University of Phoenix
- Indiana Wesleyan University

Public libraries

[edit]

The county is served by seven different public library systems:

- Crown Point Community Library has its main location with a branch in Winfield.
 [²⁴]
- East Chicago Public Library has its main location and the Robart A. Pastrick branch.[²⁵]
- Gary Public Library has its main location, the Gary Public Library and Cultural Center, and the Kennedy and Woodson branches.
- Hammond Public Library[²⁷]

- Lake County Public Library has its main location in Merrillville as well as Cedar Lake, Dyer-Schererville, Griffith-Calumet Township, Highland, Hobart, Lake Station-New Chicago, Munster and St. John branches.[²⁸]
- Lowell Public Library has its main location with branches in Schneider and Shelby.^[29]
- Whiting Public Library[³⁰]

Hospitals

[edit]

- Community Hospital, Munster 454 beds^{[31}]
- Franciscan Health Crown Point, Crown Point 203 beds (Level III Trauma Center)[³¹][³²][³³]
- Franciscan Health Dyer, Dyer 223 beds^{[31}]^{[32}]
- Franciscan Health Munster, Munster 63 beds[³¹][³²]
- Methodist Hospitals 536 beds³¹
 - $\circ\,$ Northlake Campus, Gary
 - Southlake Campus, Merrillville
- NW Indiana ER and Hospital, Hammond 6 beds^{[31}]
- St. Catherine Hospital, East Chicago 216 beds[³¹]
- St. Mary Medical Center, Hobart 215 beds^[31]
- UChicago Medicine Crown Point, Crown Point 8 beds (opening April 2024)[³⁴]

Media

The Times, based in Munster, is the largest daily newspaper in Lake County and Northwest Indiana and the second largest in the state. Lake County is also served by the *Post-Tribune*, a daily newspaper based in Merrillville.

Lakeshore Public Television operates WYIN-TV Gary on channel 56 and is the local PBS station in the Chicago television market.

These eight broadcast radio stations serve Lake County and are part of the Chicago market:

- WJOB (1230 AM) Hammond
- WWCA (1270 AM) Gary
- WLTH (1370 AM) Gary
- WLPR (89.1 FM) Lowell
- WRTW (90.5 FM) Crown Point
- WPWX (92.3 FM) Hammond
- WXRD (103.9 FM) Crown Point
- WZVN (107.1 FM) Lowell

Satellite imagery of Lake County, IN

In recent years, average temperatures in Lowell have ranged from a low of 14.4 °F (-9.8 °C) in January to a high of 83.8 °F (28.8 °C) in July, although a record low of -29 °F (-34 °C) was recorded in December 1989 and a record high of 104 °F (40 °C) was recorded in June 1988. Average monthly precipitation ranged from 1.75 inches (44 mm) in February to 4.69 inches (119 mm) in June. Temperatures at or below 0 °F (-18 °C) occur on average 11 days annually and exceed 90 °F (32 °C) degrees on 14

days.[35] In winter, lake-effect snow increases snowfall totals compared to the areas to the west.[36] In spring and early summer, the immediate shoreline areas sometimes experience lake-breeze that can drop temperatures by several degrees compared to areas further inland.[37] In summer, thunderstorms are common, occurring an average 40–50 days every year,[38] and on about 13 days, these thunderstorms produce severe winds.[39]

Government

[edit]

See also: Government of Indiana

The county government is a constitutional body, and is granted specific powers by the Constitution of Indiana, and by the Indiana Code.

County Council: The county council is the legislative branch of the county government and controls all the spending and revenue collection in the county. Representatives are elected from county districts. The council members serve four-year terms. They are responsible for setting salaries, the annual budget, and special spending. The council also has limited authority to impose local taxes, in the form of an income and property tax that is subject to state level approval, excise taxes, and service taxes. $[^{40}][^{41}]$

Board of Commissioners: The executive body of the county is made of a board of commissioners. The commissioners are elected county-wide, in staggered terms, and each serves a four-year term. One of the commissioners, typically the most senior, serves as president. The commissioners are charged with executing the acts legislated by the council, collecting revenue, and managing the day-to-day functions of the county government.[⁴⁰][⁴¹]

Court: The county maintains a small claims court that can handle some civil cases. The judge on the court is elected to a term of four years and must be a member of the Indiana Bar Association. The judge is assisted by a constable who is also elected to a four-year term. In some cases, court decisions can be appealed to the state level circuit court.[⁴¹]

County Officials: The county has several other elected offices, including sheriff, coroner, auditor, treasurer, recorder, surveyor, and circuit court clerk Each of these elected officers serves a term of four years and oversees a different part of county government. Members elected to county government positions are required to declare party affiliations and to be residents of the county.^[41]

President

Politics

[edit]

While the state of Indiana is strongly Republican, having voted Republican in every election since 1964 (except in 2008), Lake County has long been a Democratic stronghold due to being part of the Chicago metropolitan area. It has given pluralities or majorities to Democrats in every presidential election since 1932 with the exceptions of 1956 and 1972. Like the rest of the Rust Belt, however, Lake County has recently trended Republican, with Donald Trump scoring the highest percentage of the vote since 1972 in the 2024 presidential election. Lake is part of Indiana's 1st congressional district, which is held by Democrat Frank J. Mrvan.[⁴³] In the State Senate, Lake is part of the 1st, 2nd, 3rd and 6th districts, which are held by three Democrats and one Republican. In the Indiana House of Representatives, Lake is part of the 1st, 2nd, 3rd, 11th, 12th, 14th, 15th and 19th districts, which are held by four Democrats and four Republicans.

2008 presidential primary

[edit]

In the 2008 Democratic presidential primary on May 6, 2008, Lake County was one of the last counties to report results.[⁴⁵] Lake County had reported no results at 11

p.m. ET,[⁴⁶] and at midnight ET, only 28% of Lake County's vote had been reported.[⁴⁷] A large number of absentee ballots and a record turnout delayed the tallies, and polls closed an hour later than much of the state because Lake County is in the Central Time Zone.[⁴⁶] Early returns showed Senator Barack Obama leading by a potentially lead-changing margin, leaving the race between Senator Hillary Clinton and Obama "too close to call" until final tallies were reported.

Crime

The NWI Times reported that over 800 registered sex offenders live in Lake and Porter Counties of Indiana in 2021.[⁴⁸]

Culture and contemporary life

[edit]

Entertainment and the arts

[edit]

- Northwest Indiana Symphony Orchestra, concerts held at Living Hope Church Merrillville
- Theatre at the Center, located at the Center for Visual and Performing Arts Munster

Total	484,564	496,005	498,700	100.00%	100.00%	100.00%

As of the 2010 United States Census, there were 496,005 people, 188,157 households, and 127,647 families residing in the county.[57] The population density was 994.1 inhabitants per square mile (383.8/km²). There were 208,750 housing units at an average density of 418.4 per square mile (161.5/km²).[19] The racial makeup of the county was 64.4% white, 25.9% black or African American, 1.2% Asian, 0.3% American Indian, 5.8% from other races, and 2.4% from two or more races. Those of Hispanic or Latino origin made up 16.7% of the population.[57] In terms of ancestry, 16.1% were German, 11.1% were Irish, 9.6% were Polish, 5.4% were English, 4.8% were Italian and 3.7% were American.[58]

Of the 188,157 households, 34.3% had children under the age of 18 living with them, 44.7% were married couples living together, 17.4% had a female householder with no husband present, 32.2% were non-families, and 27.4% of all households were made up of individuals. The average household size was 2.60 and the average family size

was 3.19. The median age was 37.4 years.[⁵⁷]

The median income for a household in the county was \$47,697 and the median income for a family was \$58,931. Males had a median income of \$50,137 versus \$33,264 for females. The per capita income for the county was \$23,142. About 12.2% of families and 16.1% of the population were below the poverty line, including 25.3% of those under age 18 and 8.4% of those age 65 or over.[⁵⁹]

About Crown Point, Indiana

Crown Point is a city in and the region seat of Lake County, Indiana, USA. The populace was 34,884 per the 2023 American Community Survey. The city was integrated in 1868. On October 31, 1834, Solon Robinson and his household ended up being the initial inhabitants to a location that later became Crown Factor. Due to its location, Crown Point is known as the "Center of Lake County". The city is bordered by Merrillville to the north, Winfield to the east, Cedar Lake to the southwest, St. John to the west, and unincorporated Schererville to the northwest. The southerly and southwestern parts of Crown Point surround some unincorporated locations of Lake County.

About Garage door opener

A garage door opener is a motorized tool that opens and shuts a garage door managed by activate the garage wall surface. A lot of likewise include a handheld radio push-button control brought by the owner, which can be utilized to open up and close the door from a short range.
